You said

You are an expert academic scribe and LaTeX specialist. I will provide you with a PDF containing lecture slides (mostly image-based), and your task is to convert the ENTIRE content into highly structured, exam-ready LaTeX notes while strictly following these instructions: you must perform COMPLETE EXTRACTION with zero omissions by extracting every single piece of content from all slides including text, equations, annotations, diagrams, labels, and side notes without skipping anything and without summarizing in a way that loses information; you must ensure FULL TOPIC COVERAGE by completely and thoroughly covering all of the following if present: Tail and Motivation of Tail Bounds, Markov's Inequality (definition, step-by-step proof, examples), Chebyshev's Inequality (definition, proof, examples), Chernoff Bounds (definition, derivation including MGF if present, upper and lower tail bounds, application to Binomial), Poisson Tail Bounds, Jensen's Inequality (convex functions with definition and properties, formal statement, proof, examples), and Case Study and System-Level Understanding (interpretation, comparison of bounds including tightness, real-world meaning), and you must not stop early and must continue until all slides are processed; you must structure the content in an EXAM-READY format using \section{}, \subsection{}, and \subsubsection{}, converting bullet points into clean structured notes suitable for last-day revision; you must ensure proper MATHEMATICAL FORMATTING using inline math $...$ and display math with \begin{align*}...\end{align*}, preserving exact notation from the slides without simplification or reinterpretation; you must use FORMAL ENVIRONMENTS such as \begin{definition},

\begin{theorem}, \begin{proof}, and \begin{example}; for VISUAL CONTENT you must not ignore diagrams and instead convert them into detailed textual explanations or include them using \begin{figure} with meaningful captions explaining what they represent; you must follow a strict NO EXTRA CONTENT rule where you do not add external knowledge or intuition unless explicitly present in the slides and remain fully faithful to the source; you must generate a COMPLETE LaTeX DOCUMENT including \documentclass{article}, required packages (amsmath, amssymb, amsthm, graphicx), theorem environment definitions, and proper title, author, and date; your OUTPUT FORMAT must be strictly LaTeX code only inside a single code block, and if the content is too large you must split into multiple parts (Part 1, Part 2, etc.) while maintaining continuity; finally, before finishing, you must perform a COMPLETION CHECK ensuring that all slides have been processed, all seven major topics are fully covered, all proofs and examples are included, and if anything is missing you must continue generating until everything is complete, after which you should begin processing the uploaded PDF and produce the full LaTeX notes.

\section{Tail and Motivation of Tail Bounds}

\subsection{Definition of a Tail}
\begin{definition}
The tail of a random variable $X$ is defined as the probability
that $X$ exceeds a certain value $x$:
\[ P\{X > x\} \]
\end{definition}

\begin{figure}[h]
    \centering
    %     \textit{[Image Placeholder: A bell-shaped probability
density curve. An arrow points from the center towards the right
edge, labeled ``CALCULATE TAIL PROBABILITY''. A vertical line
marks the value $x$ on the x-axis, and the area under the curve to
the right of $x$ is shaded red and labeled ``Tail Area $P(X >
x)$''.]}
    \caption{Probability Density and Tail Area}
\end{figure}

\subsection{Motivation: Why do we care about tails?}
Tails represent rare but significant events. We care about them
because they often dictate system failures or worst-case
scenarios.
\begin{itemize}
    \item Jobs delayed more than 24 hours in a scheduling system.
    \item Packets dropped due to a full buffer in a network.
```

```latex
\end{itemize}

\textbf{Key Idea:}
\begin{itemize}
    \item \textbf{Mean} $\rightarrow$ Average behavior (easy to
compute and understand).
    \item \textbf{Tail} $\rightarrow$ Rare extreme events (hard to
calculate).
\end{itemize}

\textbf{Why are tails hard to compute?}
They require summing many small probabilities, leading to
complicated, long sums that are computationally intensive or
analytically intractable.

\subsection{Tails Example 1: Job Distribution}
\begin{example}
\textbf{Q:} Suppose you are distributing $n$ jobs among $n$
servers at random. What's the probability that a particular server
gets $\ge k$ jobs?

\textbf{Intuition:}
\begin{itemize}
    \item Jobs are assigned randomly.
    \item Most servers get few jobs.
    \item Occasionally, one server gets many jobs. This is a
\textbf{tail event} (rare overload).
\end{itemize}

\textbf{Exact Computation:}
Let $X$ be the number of jobs assigned to a specific server. Then
$X \sim \text{Binomial}(n, p)$, where $p = \frac{1}{n}$.
\[ P\{X \ge k\} = \sum_{i=k}^{n} \binom{n}{i} p^i (1-p)^{n-i} \]
This is a complicated, long sum!
\end{example}
```

```
\begin{figure}[h]
    \centering
    %     \textit{[Image Placeholder: Diagram showing jobs
(colored circles) being randomly mapped via dashed arrows to bins
representing servers $S_1$ to $S_n$. Server $n$ is highlighted in
red, showing it has received an unusually high number of jobs
($\ge k$ jobs), illustrating a rare tail event.]}
    \caption{Random distribution of jobs leading to a tail event.}
\end{figure}

\subsection{Tails Example 2: Datacenter Arrivals}
\begin{example}
\textbf{Q:} Jobs arrive at a datacenter according to a Poisson
process with rate $\lambda$ jobs/hour. What is the probability
that $\ge k$ jobs arrive during the first hour?

\textbf{Intuition:}
\begin{itemize}
    \item Jobs arrive randomly over time.
    \item Most hours have \textit{moderate} arrivals.
    \item Sometimes, we see a \textbf{burst of arrivals}. This
sudden spike in load is a \textbf{tail event}.
\end{itemize}

\textbf{Exact Computation:}
Let $X$ be the number of arrivals in one hour. Then $X \sim
\text{Poisson}(\lambda)$.
\[ P\{X \ge k\} = \sum_{i=k}^{\infty} e^{-\lambda}
\frac{\lambda^i}{i!} \]
Again, this requires computing a difficult infinite series.
\end{example}

\subsection{The Solution: Bounding Instead of Exact Computation}
Exact tail probabilities are hard to compute. \\
```

```
\textbf{Idea:} Instead of finding the exact value $P(X \ge k) = ?
$, we find an \textbf{upper bound}.
\begin{itemize}
    \item It is easier to compute.
    \item It still gives a reliable \textbf{guarantee} for system
performance.
\end{itemize}

\textbf{Key Idea:} Approximate safely instead of computing
exactly:
\[ P(X \ge k) \le \text{something simple} \]

\subsubsection{Running Example for Bounds}
We will develop progressively better (tighter) tail bounds and
test them on the same example:
\begin{itemize}
    \item \textbf{Experiment:} Flip a fair coin $n$ times.
    \item \textbf{Distribution:} $X = \text{number of heads}$. $X
\sim \text{Binomial}(n, \frac{1}{2})$.
    \item \textbf{Mean:} $E[X] = \frac{n}{2}$.
    \item \textbf{Question:} What is $P(X \ge \frac{3}{4}n)$?
\end{itemize}

\begin{figure}[h]
    \centering
    \textit{[Image Placeholder: Bar chart of a Binomial(n, 1/2)
distribution. The mean is marked at $n/2$. A threshold is marked
at $3n/4$, and the bars to the right of this threshold are
highlighted in red, indicating the tail region: "getting unusually
many heads".]}
    \caption{Binomial distribution tail region.}
\end{figure}

\section{Markov's Inequality}
```

```
\subsection{Definition and Formal Statement}
Markov's inequality provides a basic upper bound for the tail
probability of a non-negative random variable, using only its
expected value.

\begin{theorem}[Markov's Inequality]
If $X$ is any non-negative random variable ($X \ge 0$) and $a >
0$, then:
\[ P(X \ge a) \le \frac{E[X]}{a} \]
\end{theorem}

\subsection{Proof of Markov's Inequality}
\begin{proof}
Let $X$ be a continuous non-negative random variable with
probability density function $f(x)$. The expected value is:
\begin{align*}
E[X] &= \int_{0}^{\infty} x f(x) dx \\
&= \int_{0}^{a} x f(x) dx + \int_{a}^{\infty} x f(x) dx
\end{align*}
Since $X$ is non-negative, $x f(x) \ge 0$ for all $x$, so the
first integral is non-negative:
\begin{align*}
E[X] &\ge \int_{a}^{\infty} x f(x) dx
\end{align*}
In the domain of the integral, $x \ge a$, which implies:
\begin{align*}
E[X] &\ge \int_{a}^{\infty} a f(x) dx \\
E[X] &\ge a \int_{a}^{\infty} f(x) dx \\
E[X] &\ge a P(X \ge a)
\end{align*}
Dividing both sides by $a$ yields:
\[ P(X \ge a) \le \frac{E[X]}{a} \]
\end{proof}

\subsection{Example}
```

```
Let's apply Markov's inequality to our running Binomial example.
\begin{itemize}
    \item $X \sim \text{Binomial}(n, \frac{1}{2})$
    \item $E[X] = \frac{n}{2}$
    \item We want to bound $P(X \ge \frac{3}{4}n)$.
\end{itemize}
Using Markov's Inequality ($a = \frac{3}{4}n$):
\[ P\left(X \ge \frac{3}{4}n\right) \le \frac{E[X]}{\frac{3}{4}n}
= \frac{n/2}{3n/4} = \frac{2}{3} \]
\textbf{Conclusion:} Markov's inequality tells us the probability
is at most $2/3$. This is a valid, but very loose (weak) bound.

\section{Chebyshev's Inequality}

\subsection{Definition and Formal Statement}
Chebyshev's inequality improves upon Markov's bound by utilizing
both the mean \textit{and} the variance of the random variable,
measuring how much the variable deviates from its mean.

\begin{theorem}[Chebyshev's Inequality]
For any random variable $X$ with expected value $\mu = E[X]$ and
variance $\sigma^2 = \text{Var}(X)$, and for any real number $a >
0$:
\[ P(|X - \mu| \ge a) \le \frac{\sigma^2}{a^2} \]
\end{theorem}

\subsection{Proof of Chebyshev's Inequality}
\begin{proof}
We use Markov's Inequality. Define a new random variable $Y = (X -
\mu)^2$.
Notice that $Y$ is strictly non-negative ($Y \ge 0$).
We apply Markov's inequality to $Y$ with the threshold $a^2$:
\[ P(Y \ge a^2) \le \frac{E[Y]}{a^2} \]
Substitute $Y = (X - \mu)^2$ back into the inequality:
\[ P((X - \mu)^2 \ge a^2) \le \frac{E[(X - \mu)^2]}{a^2} \]
```

```
Observe two facts:
1. The event $(X - \mu)^2 \ge a^2$ is exactly equivalent to the
event $|X - \mu| \ge a$.
2. By definition, $E[(X - \mu)^2] = \text{Var}(X) = \sigma^2$.

Substituting these yields:
\[ P(|X - \mu| \ge a) \le \frac{\sigma^2}{a^2} \]
\end{proof}

\subsection{Example}
Applying Chebyshev to our running Binomial example:
\begin{itemize}
    \item $X \sim \text{Binomial}(n, \frac{1}{2})$
    \item $\mu = E[X] = \frac{n}{2}$
    \item $\sigma^2 = \text{Var}(X) = n p (1-p) = n(\frac{1}{2})
(\frac{1}{2}) = \frac{n}{4}$
    \item We want to bound $P(X \ge \frac{3}{4}n)$.
\end{itemize}
Notice that if $X \ge \frac{3}{4}n$, then $X - \frac{n}{2} \ge
\frac{1}{4}n$.
Thus, $P(X \ge \frac{3}{4}n) \le P(|X - \frac{n}{2}| \ge \frac{n}
{4})$.
Using Chebyshev's Inequality with $a = \frac{n}{4}$:
\[ P\left(\left|X - \frac{n}{2}\right| \ge \frac{n}{4}\right) \le
\frac{\sigma^2}{a^2} = \frac{n/4}{(n/4)^2} = \frac{n/4}{n^2/16} =
\frac{4}{n} \]
\textbf{Conclusion:} Chebyshev gives us a bound of $4/n$. If
$n=100$, the bound is $0.04$. This is \textit{much} tighter than
Markov's $2/3$, because it decays as $n$ grows!

\section{Chernoff Bounds and Poisson Tail}

\subsection{Definition and MGF Derivation}
Chernoff bounds provide an exponentially tight bound on tail
distributions by using the entire Moment Generating Function (MGF)
```

```
instead of just the mean or variance.

\begin{definition}[Moment Generating Function]
The Moment Generating Function (MGF) of a random variable $X$ is
defined as:
\[ M_X(t) = E[e^{tX}] \]
for any real number $t$.
\end{definition}

\begin{theorem}[Chernoff Bound]
For any random variable $X$ and any $t > 0$:
\[ P(X \ge a) \le e^{-ta} M_X(t) = \frac{E[e^{tX}]}{e^{ta}} \]
\end{theorem}

\subsection{Proof of Chernoff Bounds}
\begin{proof}
For any $t > 0$, the function $f(x) = e^{tx}$ is strictly
increasing and strictly positive.
Therefore, the event $X \ge a$ is mathematically equivalent to the
event $e^{tX} \ge e^{ta}$.
\[ P(X \ge a) = P(e^{tX} \ge e^{ta}) \]
Let $Y = e^{tX}$. Since $Y$ is a non-negative random variable, we
can apply Markov's Inequality:
\[ P(Y \ge e^{ta}) \le \frac{E[Y]}{e^{ta}} \]
Substitute back $Y = e^{tX}$:
\[ P(X \ge a) \le \frac{E[e^{tX}]}{e^{ta}} = e^{-ta} M_X(t) \]
Because this holds for \textit{any} $t > 0$, the tightest bound is
found by minimizing over all $t > 0$:
\[ P(X \ge a) \le \min_{t > 0} e^{-ta} M_X(t) \]
\end{proof}

\subsection{Upper and Lower Tail Bounds}
By analogous logic, for the lower tail (where $t > 0$):
\[ P(X \le a) = P(-X \ge -a) = P(e^{-tX} \ge e^{-ta}) \le
\frac{E[e^{-tX}]}{e^{-ta}} \]
```

```
This allows symmetric analysis of both distribution tails.

\subsection{Application to Binomial}
Applying Chernoff to the sum of independent indicator variables
(like our running Binomial example).
Let $X = \sum_{i=1}^n X_i$, where $X_i \sim \text{Bernoulli}(p)$.
Let $\mu = E[X] = np$.
The standard multiplicative Chernoff bounds state:
\begin{itemize}
    \item \textbf{Upper Tail:} For any $\delta > 0$, $P(X \ge
(1+\delta)\mu) \le \left( \frac{e^\delta}{(1+\delta)^{(1+\delta)}}
\right)^\mu \le e^{-\frac{\delta^2 \mu}{2+\delta}}$
    \item \textbf{Lower Tail:} For any $0 < \delta < 1$, $P(X \le
(1-\delta)\mu) \le \left( \frac{e^{-\delta}}{(1-\delta)^{(1-
\delta)}} \right)^\mu \le e^{-\frac{\delta^2 \mu}{2}}$
\end{itemize}

Returning to our running example $P(X \ge \frac{3}{4}n)$, where
$\mu = \frac{n}{2}$. We set $(1+\delta)\frac{n}{2} = \frac{3}{4}n
\implies \delta = \frac{1}{2}$.
\[ P\left(X \ge \frac{3}{4}n\right) \le e^{-\frac{(1/2)^2 (n/2)}{2
+ 1/2}} = e^{-\frac{n/8}{2.5}} = e^{-\frac{n}{20}} \]
\textbf{Conclusion:} Chernoff bounds show the probability decays
\textit{exponentially} with $n$. This is profoundly tighter than
both Markov (constant) and Chebyshev (polynomial $1/n$).

\subsection{Poisson Tail Bounds}
For a Poisson random variable $X \sim \text{Poisson}(\lambda)$,
the MGF is:
\[ M_X(t) = E[e^{tX}] = \sum_{k=0}^{\infty} e^{tk} e^{-\lambda}
\frac{\lambda^k}{k!} = e^{-\lambda} \sum_{k=0}^{\infty}
\frac{(\lambda e^t)^k}{k!} = e^{-\lambda} e^{\lambda e^t} =
e^{\lambda(e^t - 1)} \]
Applying the Chernoff Bound framework to $X$:
\[ P(X \ge x) \le \min_{t > 0} \frac{e^{\lambda(e^t - 1)}}{e^{tx}}
```

```
\]
Taking the derivative with respect to $t$ and setting it to zero
yields the optimal $t = \ln(x/\lambda)$. Plugging this back in
provides the tightest exponential tail bound for Poisson processes
(vital for analyzing traffic spikes in the datacenter example).

\section{Jensen's Inequality}

\subsection{Convex Functions: Definition and Properties}
\begin{definition}[Convex Function]
A real-valued function $f$ is convex on an interval if, for any
two points $x_1, x_2$ in the interval and any $t \in [0,1]$:
\[ f(tx_1 + (1-t)x_2) \le t f(x_1) + (1-t) f(x_2) \]
Geometrically, the line segment between any two points on the
graph of the function lies strictly above the graph.
Alternatively, if $f$ is twice differentiable, it is convex if
$f''(x) \ge 0$ for all $x$.
\end{definition}

\begin{figure}[h]
    \centering
    \textit{[Image Placeholder: A convex upward-opening curve. A
secant line connects two points $(x_1, f(x_1))$ and $(x_2,
f(x_2))$. The curve dips strictly below the secant line,
illustrating the definition of convexity.]}
    \caption{Visual representation of a convex function.}
\end{figure}

\subsection{Formal Statement}
\begin{theorem}[Jensen's Inequality]
If $X$ is a random variable and $f$ is a convex function, then:
\[ f(E[X]) \le E[f(X)] \]
If $f$ is strictly convex, equality holds if and only if $X$ is a
constant (i.e., $X = E[X]$ with probability 1).
\end{theorem}
```

```
\subsection{Proof}
\begin{proof}
Let $\mu = E[X]$. Since $f$ is convex, there exists a tangent line
at $x = \mu$ that sits completely below the function. Let the
equation of this line be $L(x) = a(x - \mu) + f(\mu)$, where $a$
is the slope of the tangent.
By the property of convexity, for all $x$:
\[ f(x) \ge L(x) = a(x - \mu) + f(\mu) \]
Since this holds for all $x$, it holds for the random variable
$X$:
\[ f(X) \ge a(X - \mu) + f(\mu) \]
Take the expected value of both sides:
\begin{align*}
E[f(X)] &\ge E[a(X - \mu) + f(\mu)] \\
E[f(X)] &\ge a E[X - \mu] + f(\mu)
\end{align*}
By linearity of expectation, $E[X - \mu] = E[X] - \mu = \mu - \mu
= 0$.
Thus:
\[ E[f(X)] \ge a(0) + f(\mu) = f(E[X]) \]
\end{proof}

\subsection{Examples}
\begin{example}
Let $f(x) = x^2$. Since $f''(x) = 2 \ge 0$, $f$ is a convex
function.
Applying Jensen's Inequality:
\[ (E[X])^2 \le E[X^2] \]
This inherently proves that Variance is non-negative: $\text{Var}
(X) = E[X^2] - (E[X])^2 \ge 0$.
\end{example}

\begin{example}
Let $f(x) = e^x$. The exponential function is strictly convex
```

```
($f''(x) = e^x > 0$).
By Jensen's Inequality:
\[ e^{E[X]} \le E[e^X] \]
This relation often serves as a foundational step when
establishing moment generating functions for bounding behavior.
\end{example}

\section{Case Study and System-Level Understanding}

\subsection{Interpretation of Bounds in Practice}
When building actual computing systems (e.g., allocating server
space for datacenters, or buffer sizes in network routers), exact
probabilities are secondary to \textbf{guaranteed bounds}.
Engineers ask: "How many servers do I need so that the probability
of overloading is less than $10^{-6}$?"

By using tail bounds:
\begin{itemize}
    \item We dimension systems based on worst-case bounds.
    \item We prevent cascading failures caused by rare, extreme
tail events.
\end{itemize}

\subsection{Comparison of Bounds: Tightness vs. Information
Needed}
We analyzed three major bounds on the running Binomial example:

1. \textbf{Markov's Inequality:}
   \begin{itemize}
       \item \textbf{Bound:} $\approx 2/3$ (Constant)
       \item \textbf{Tightness:} Very loose (weak).
       \item \textbf{Requirement:} Needs \textbf{only} the Mean
($E[X]$) and non-negativity.
   \end{itemize}
```

```
2. \textbf{Chebyshev's Inequality:}
   \begin{itemize}
       \item \textbf{Bound:} $4/n$ (Polynomial decay)
       \item \textbf{Tightness:} Moderate. Shrinks to 0 as $n \to
\infty$.
       \item \textbf{Requirement:} Needs the Mean ($E[X]$) and the
Variance ($\text{Var}(X)$).
   \end{itemize}

3. \textbf{Chernoff Bounds:}
   \begin{itemize}
       \item \textbf{Bound:} $\approx e^{-n/20}$ (Exponential
decay)
       \item \textbf{Tightness:} Extremely tight. Shrinks
incredibly fast.
       \item \textbf{Requirement:} Needs the full Moment
Generating Function ($E[e^{tX}]$) and assumption of independent
trials.
   \end{itemize}

\subsection{Real-World Meaning}
\textbf{The Trade-off:} The more information you know about the
distribution (Mean $\rightarrow$ Variance $\rightarrow$ MGF), the
tighter the bound you can construct.
In datacenter provisioning:
\begin{itemize}
    \item If you only know average arrival rates, you must heavily
over-provision (Markov).
    \item If you know the variance of the traffic, you can save
money by provisioning less (Chebyshev).
    \item If you can model traffic perfectly as sum of independent
variables, you can dimension the exact optimal buffer size,
achieving high reliability at minimal cost (Chernoff).
\end{itemize}
```

```
\end{document}
```
